Accelerate Python Loops with the Intel [®] ALAnalytics Toolkit

Workshop #2 in series Module 2: Broadcasting, NumPy Where, NumPy Select

Bob Chesebrough AI Software Solutions Engineer

Learning Objectives

• At the end of the workshop you will be able to:

- Describe a Python loop replacement strategy using NumPy constructs which improves readability, maintainability, performs fasts on current hardware and readies code for future HW & SW accelerations that Intel builds into silicon and which are exposed via NumPy
- Describe NumPy clause to aid sorting, aggregations, reductions, broadcasting, and "where" and "select" to significantly accelerate your Python code
- Describe the value of the Intel oneAPI AI Analytics Toolkit
- Describe underlying reasons for the acceleration due to NumPy powered by oneAPI

Intel[®] oneAPI AI Analytics Toolkit

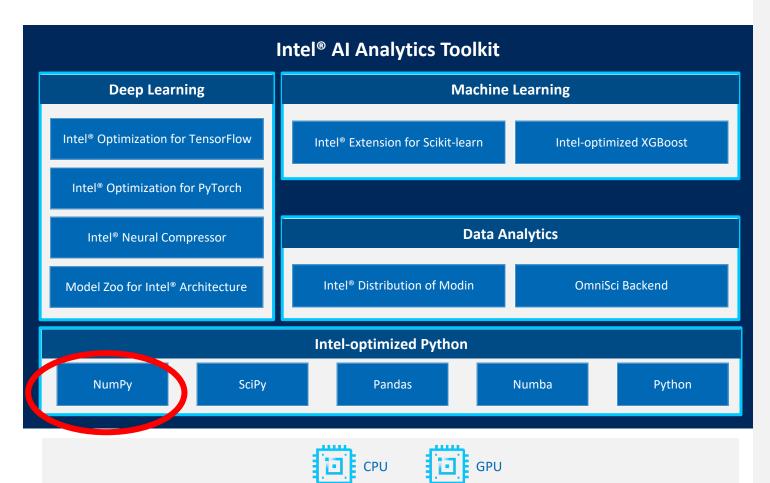

Accelerate end-to-end AI and data analytics pipelines with libraries optimized for Intel[®] architectures

Who Uses It?

Data scientists, AI researchers, ML and DL developers, AI application developers

Top Features/Benefits

- Deep learning performance for training and inference with Intel optimized DL frameworks and tools
- Drop-in acceleration for data analytics and machine learning workflows with compute-intensive Python packages

Hardware support varies by individual tool. Architecture support will be expanded over time.

3

Intel[®] AI Analytics Toolkit

Deep Learning	Machine	Learning
Intel [®] Optimization for TensorFlow	Intel [®] Extension for Scikit-learn	Intel-optimized XGBoost
Intel [®] Optimization for PyTorch		
Intel [®] Neural Compressor	Data Analytics	
Model Zoo for Intel® Architecture	Intel [®] Distribution of Modin	OmniSci Backend
	Intel-optimized Python	
NumPy SciPy	Pandas	Numba Python

Hardware support varies by individual tool. Architecture support will be expanded over time.

Numpy – powered by oneAPI

- Stock version has oneAPI included
- Download oneAPI analytics toolkit <u>here</u> (get latest functionality here first)
- Are you getting the performance you expect using NumPy?
- Are you using NumPy effectively?
- Note: Keep NumPy library up to date
- Are you using NumPy effectively?

Python is Great & Fast ...

- For rapidly proto typing ideas
- Tackling just about every imaginable coding task
- Getting project rolling quickly ... Examples of code are everywhere
- Easy: Dynamically typed making programming easy
- Easy & Fast: : Leverage huge number of libraries, easily installable
- For AI: fast/no porting: easy portability of models across architectures

Python is SLOW

- For some things:
- **REPEATED** low level tasks
- Large loops
- Nested Loops
- List comprehensions (if large)
- BUT
- There are ways to mitigate its weaknesses
- Take advantage of those libraries
- NUMPY this is powered by oneAPI !
- And others!

Numpy Vectorization:

 This practice of replacing explicit loops with array expressions is commonly referred to as vectorization. In general, vectorized array operations will often be one or two (or more) orders of magnitude faster than their pure Python equivalents, with the biggest impact [seen] in any kind of numerical computations. - Wes McKinney

Vectorization is NOT just theory!

You will see, hear about the speedups possible, then you will experience it in code

This is why we strongly encourage the use of libraries powered by Intel oneAPI such as Numpy, Scipy, and the rest

Get the goodness of Python but inherit vectorization speed inherent with Numpy powered by Intel oneAPI

100 X speed up using Numpy broadcasting versus loop

Optimization Notice

Why are these speedup so dramatic?

- Numpy takes advantage of vectorization: powered by Intel oneAPI
- Specifically, oneMKL, for vectorization
- Vector width allows multiple operations in single HW instruction.
- Many FP instructions computed in single instruction

AVX2: 256 bits: 8 floats wide

AVX512: 512 bits: 16 floats wide

SIMD in a Nutshell

Loopy: (done one at a time) for i in range(1,8): c[i] = a[i] + b[i]

SIMD: (all 8 locations done at once via SIMD instructions) c = a + b

Optimization Notice Copyright © 2022, Intel Corporation. All rights reserved. *Other names and brands may be claimed as the property of others.

We are comparing to simple loops in Python

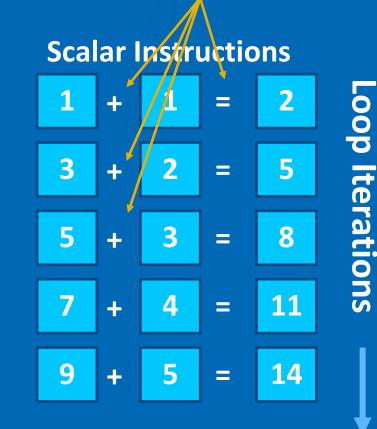

In python, these operations are COSTLY

Python is dynamically typed

• Has to **check** the data type before any operation to ensure correct operations are applied

Even a simple integer is not simple

- A class or structure that contains
 - reference counters and other values
 - These are updated every operation

Effect of Non Contiguous Memory Access

A list of integers in python are NOT generally in contiguous locations

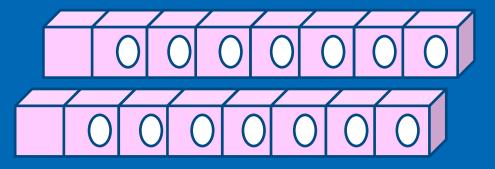

For this list: [1, 2, 3, 4, 5, 6, 7, 8]

Accessing many of these in loops is VERY Costly (could be hundreds of clock cycles)

	5	7

Cache is used ineffectively

Random reads from all over memory hurt performance

Modern Intel CPU's read in Cache line of consecutive memory so that consecutive data is already to go when needed. The cache line may contain 16 consecutive elements or more

But with random reads, our next data element is read from a completely different place in memory – wasting the remaining elements that were ready to be served from the cache line

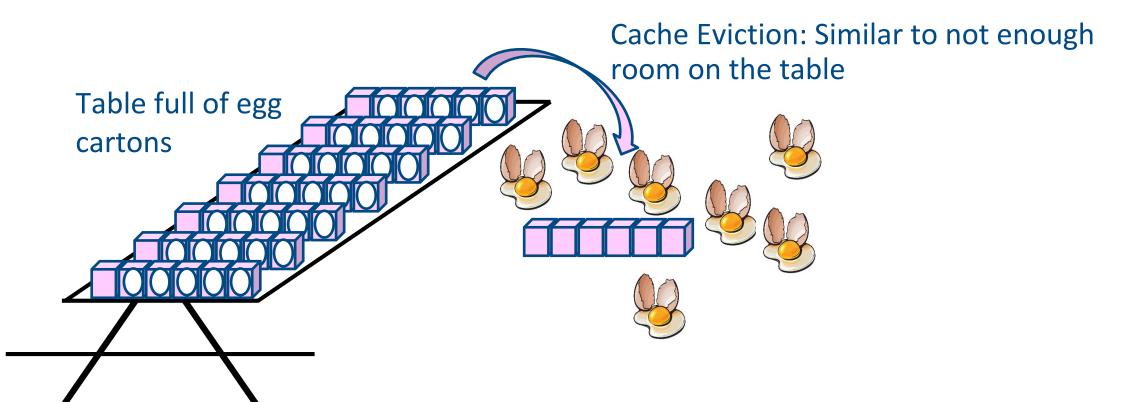

This is analogous to a chef opening and cooking a single egg from a carton of 16 to service customer number 1

Then then opening a NEW carton of eggs from a SECOND carton for customer number 2. The other eggs get tossed out [analogous to cache line eviction]

These are SOME reasons why vectorization is better – it mitigates all the above

Cache is used ineffectively with random memory accesses

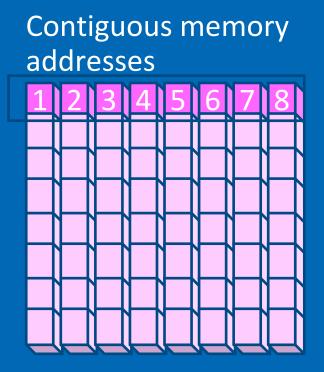

Optimization Notice Copyright © 2022, Intel Corporation. All rights reserved. *Other names and brands may be claimed as the property of others.

Additionally: concerning memory

An array of integers in Numpy are contiguous locations

Modern CPU's return a cache line (like a carton of eggs) for the contiguous memory elements nearby one you chose to load initially.

The assumption is: if I just used memory address 0x12345, then likely I will use 0x12346 very soon

How do I move my code patterns to NumPy?

- NumPy Vectorization encompasses...
- NumPy Universal Functions (Ufuncs)
- Aggregations
- Fancy Indexing
- Broadcasting
- NumPy Where & Select for Conditionals
- Are ALL loops vectorizable?
- We will give guidance

How to create Numpy arrays

• From existing lists:

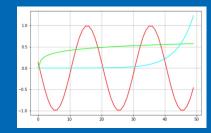

• By dimensions but empty:

np.ndarray(shape=(2,2), dtype=float,

• By Shape – fill with zeros or ones:

>>> s = (2,2)
>>> np.zeros(s)
array([[0., 0.],
 [0., 0.]])

ufuncs

ufuncs are written in C (for speed) and linked into Python with NumPy's ufunc facility

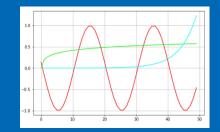

Universal Functions	Description: These are vectorized
Math operations	add, subtract, multiply, divide, reciprocal, matmul, log, exp, square, sqrt,
Trigonometric	sin, cos, tan, arcsin, arccos, arctan, hypot, sinh, cosh, tanh, degrees, radians
Bit-twiddling	bitwise_and, bitwise_or, bitwise_xor, invert, left_shift, right_shift
Comparison Functions	greater, greater_equal, less, less_equal, not_equal, equal, logical_and, logical_or, logical_xor, logical_not
Floating Functions	isfinite, isinf, isnan, isnat, fabs, signbit, copysign, nextafter, spacing, modf, ldexp, frexp, fmod, floor, ceil, trunc

NumPy Universal functions (ufunc): Vectorized!

- Implements vectorization support in Intel AVX2 and AVX512
- Takes a fixed number of specific inputs
- Produces a fixed number of specific outputs
- Applies function in per element-wise fashion.
- For detailed information on universal functions, see <u>Universal functions (ufunc) basics</u>.

```
import numpy as np
arr = np.trunc([-3.1666, 3.6667])
print(arr)
out:
[-3. 3.]
```

Sophisticated Indexing

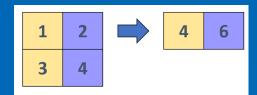

• Slicing and Indexing can replace many common loop concepts

```
a = np.arange(100_000_000)
t1 = time.time()
b = np.arange(50_000_002)
N = len(a)
for i in range (N):
    if i % 2 == 0:
        b[i//2] = a[i]
t2 = time.time()
```

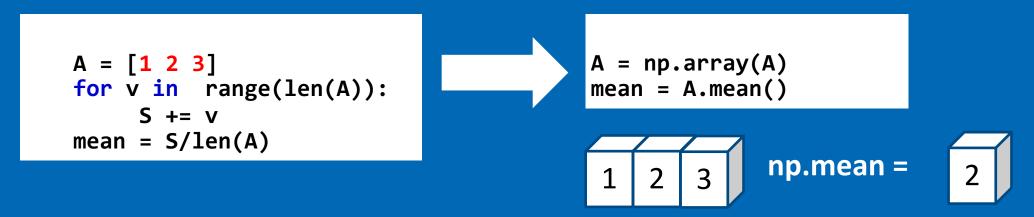

NumPy Aggregation & Statistics Functions

Functions	Description: These are vectorized
np.mean()	Compute the arithmetic mean along the specified axis.
np.std()	Compute the standard deviation along the specified axis.
np.var()	Compute the variance along the specified axis.
np.sum()	Sum of array elements over a given axis.
np.prod()	Return the product of array elements over a given axis.
np.cumsum()	Return the cumulative sum of the elements along a given axis.
np.cumprod()	Return the cumulative product of elements along a given axis.
np.min(), np.max()	Return the minimum / maximum of an array or minimum along an axis.
np.argmin() <i>,</i> np.argmax()	Returns the indices of the minimum / maximum values along an axis
np.all()	Test whether all array elements along a given axis evaluate to True.
np.any()	Test whether any array element along a given axis evaluates to True.

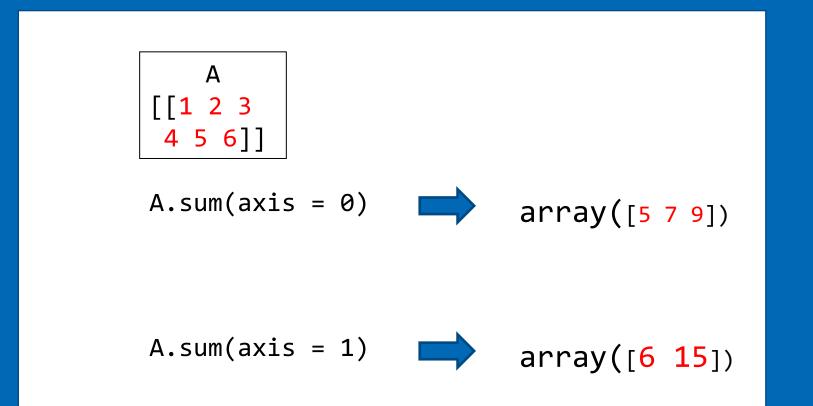

NumPy Aggregations: Vectorized!

- Aggregation is an operation to reduce the dimensionality of an array or vector
- Implements vectorization support in Intel AVX2 and AVX512
- Replace loops you are using to compute averages, sums, standard deviation, min, max etc
- Use numpy aggregation instead. Its more readable, faster, and future proof

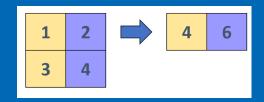

NumPy Aggregations: Vectorized! Aggregations can be applied along different axes

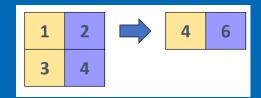

25

Aggregation: Example

a = np.arange(1_000_000).reshape(1000,1000)
t1 = time.time()
N = len(a)
sum = 0
for i in range (N):
 for j in range(N):
 sum += a[i,j]
t2 = time.time()

LOOX speed up over naïve loop

Optimization Notice Copyright © 2022, Intel Corporation. All rights reserved. *Other names and brands may be claimed as the property of others.

NumPy: Aggregation & Statistics

a =	np.arange(100_000_000)
sum	= []
s =	0
£	i in range (N):
TOP	
TOP	s += a[i]

Result: 100 Million elements: roughly 130

Optimization Notice Copyright © 2022, Intel Corporation. All rights reserved. *Other names and brands may be claimed as the property of others.

NumPy: Sorting: Quicksort

```
def quickSort(arr, low, high):
    if low < high:
        pivotIndex = partition(arr, low, high)
        quickSort(arr, low, pivotIndex - 1)
        quickSort(arr, pivotIndex + 1, high)
def partition(arr, low, high):
    pivot = arr[high]
    i = low - 1 # Index of smaller element
    for j in range(low, high):
        # If current element is smaller than or equal to pivot
                                                                np.sort(arr, axis=None, kind='quicksort')
        if arr[j] <= pivot:</pre>
            i += 1
            arr[i], arr[j] = arr[j], arr[i]
    arr[i+1], arr[high] = arr[high], arr[i+1]
    return i + 1
```

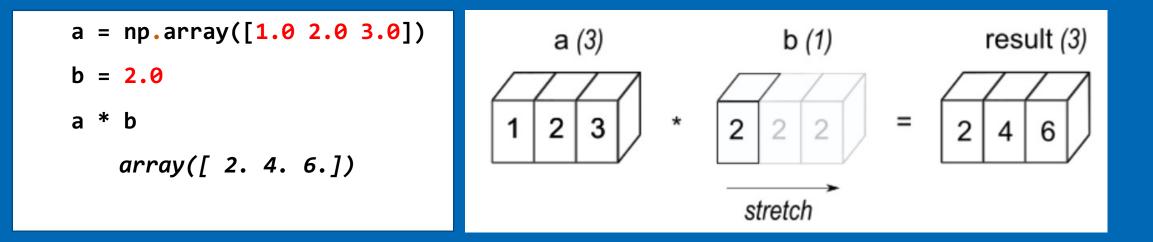

Result: 1 Million elements: roughly 873

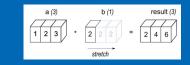

Link to Intel NumPy article

NumPy Broadcasting: Vectorized!

- Support with AVX2 and AVX512 instructions
- Apply an operator with a scalar to each element in vector
- Also, apply operator with lower dimension vector to larger dimension

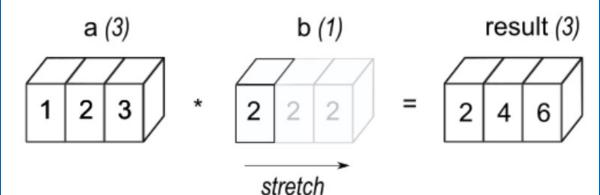

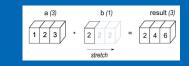

Broadcasting Graphically

Non-matching dimensions are extended and data copied at HW level Once dimensions match the vectors can be added, subtracted etc

First example:

- a.shape (1, 3)
- b.shape (1,1) # extend/copy to (1, 3)
- result.shape (1, 3)

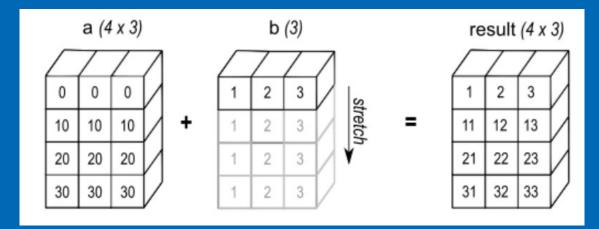

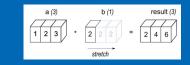

Broadcasting Graphically

Non-matching dimensions are extended and data copied at HW level Once dimensions match the vectors can be added, subtracted etc

Second example:

- a.shape (4, 3)
- b.shape (1, 3) # extend/copy to (4, 3)
- result.shape (4, 3)

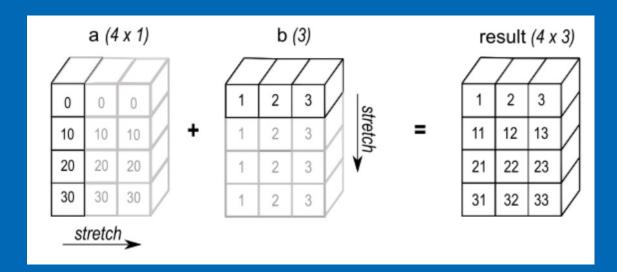

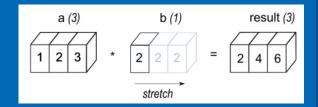

Broadcasting Graphically

Non-matching dimensions are extended and data copied at HW level Once dimensions match the vectors can be added, subtracted etc

Third example:

- a.shape (4, 1)
- b.shape (1, 3) # extend/copy to (4, 3)
- result.shape (4, 3)

Broadcasting Example

Simple Multiplication table

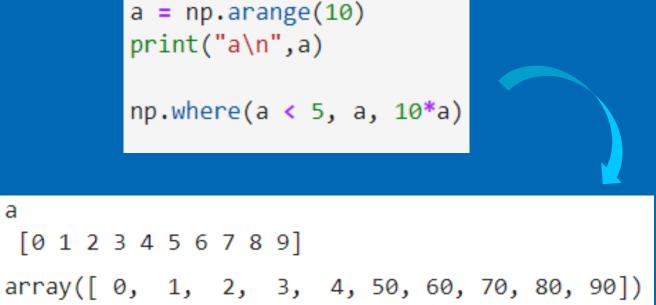

B = np.zeros((N,N))
for i in range(N):
 for j in range(N):
 B[i,j] = (i+1)*(j+1)

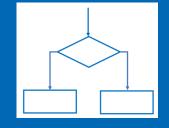

Optimization Notice

Numpy.where

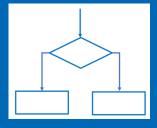

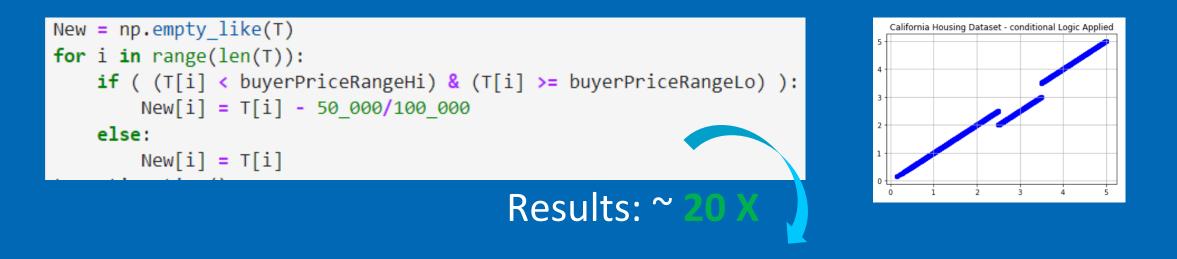

а

NumPy Where, NumPy Select

- If statements (conditional logic) might severely limit performance:
- Numpy: handles conditionals quickly, efficiently

New = np.where((T < buyerPriceRangeHi) & (T >= buyerPriceRangeLo), T - 50_000/100_000, T)

Numpy Where

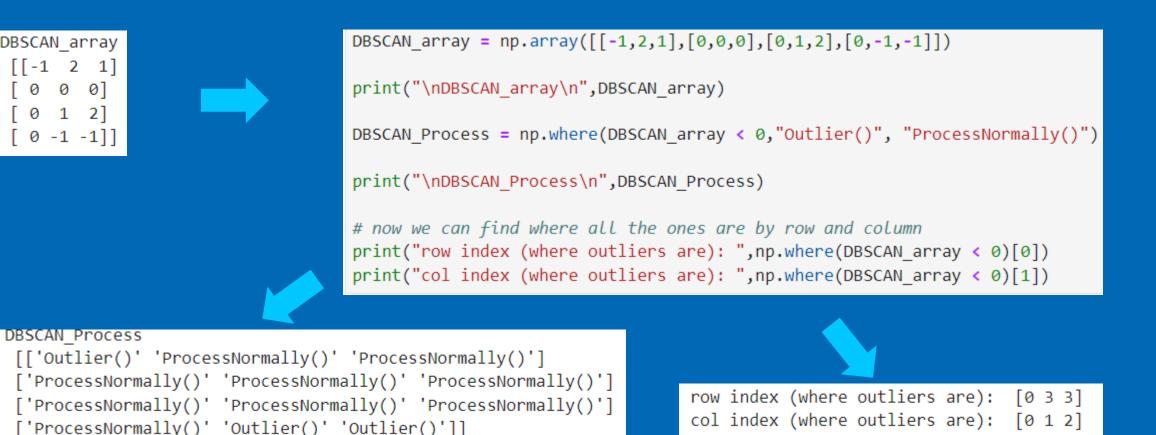

DBSCAN array [[-1 2 1]

0 01

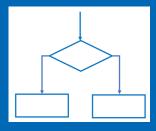

0 -1 -1]]

2]

Find row, col indices fast

Numpy.where: More Complex logic

one solution - preserves the indexing edges for easy checking
res = np.where((MultiplicationTable%12 == 0) | (MultiplicationTable%9 == 0) , MultiplicationTable, 0)
res[0,:] = MultiplicationTable[0,:]
res[:,0] = MultiplicationTable[:,0]

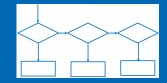

Results:

 \sim

Numpy Select

Numpy.select: see

- Return an array drawn from elements in choice list, depending on conditions.
- Great for pulling together elements or functions(elements) from different arrays, DataFrames, different parts of the same array, etc

```
x = np.arange(6)
print("X\n",x)
condlist = [x<3, x>3]
choicelist = [x, x**2]
np.select(condlist, choicelist, 42)
```

Numpy: Select Example

```
for i in range(BIG):
    if A[i,4] == 10:
        A[i,5] = A[i,2] * A[i,3]
    elif (A[i,4] < 10) and (A[i,4] >=5):
        A[i,5] = A[i,2] + A[i,3]
    elif A[i,4] < 5:
        A[i,5] = A[i,0] + A[i,1]</pre>
```

```
Results: ~ 20 X
```

The Pandas Connection

- Pandas is built on top of Numpy
- All the methods describe before apply
- We will demonstrate alternative ways to achieve speedups when Pandas Apply is slow due to conditional logic in the custom called function

Methods

- Use "Apply" for simple functions to apply to columns
- When things get slow, convert data to Numpy arrays
- to_numpy()
- Replace conditional logic in the Apply with Numpy.Where or Numpy.Select
- It is even possible to use Numpy. Select to manipulate Pnadas dataframes directly

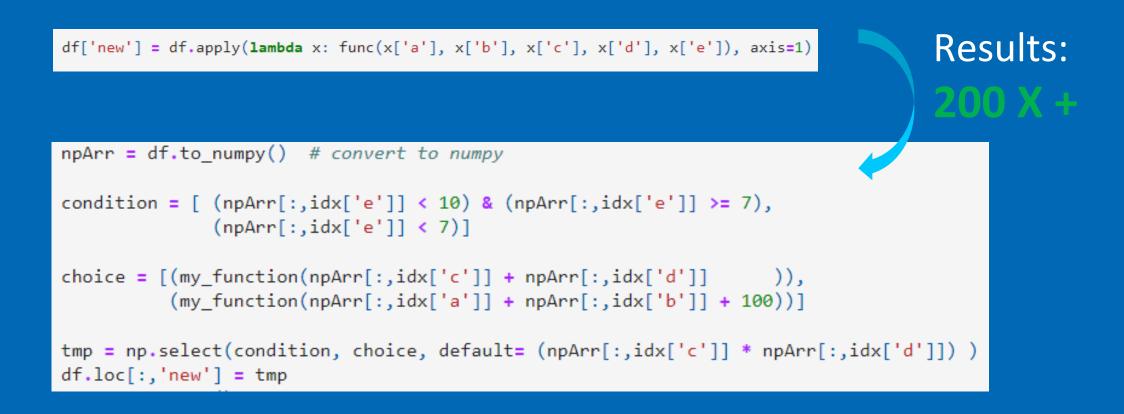

Using Numpy.Select as alternative to Pandas.Apply

df['new'] = df.apply(lambda x: func(x['a'], x['b'], x['c'], x['d'], x['e']), axis=1)

```
def my_function(x):
    return np.log(1+x)

def func(a,b,c,d,e):
    if e == 10:
        return c*d
    elif (e < 10) and (e>=7):
        return my_function(c+d)
    elif e < 7:
        return my_function(a+b+100)
</pre>
```

Using Numpy.Select as alternative to Pandas.Apply

Call to Action

- Loops:
- Find **large** single, double, and triple nested **loops** in your code and replace with Scipy/ Scikit-Learn*, or Numpy alternative
- Find time consuming list comprehensions and replace with a Numpy alternative .
- If statements:
- replace with Numpy.where or Numpy.select options if possible
- Using array masking that follows the conditional logic

Thanks for attending the session
